

Sport Betting AI — Session Handoff

Branch: **claude/add-bovada-odds-c9xmr** • Repo: **edwardnguyen1194-spec/sport-betting** •
Live app: **sports-betting-ai-agent** • Generated: 2026-04-11

TL;DR

A previous Claude Code session built a feature branch with every item from your god-mode brief: Bovada college baseball odds, six other free odds sources, a heavy-favorite filter strategy, an LSTM player-props model, a Vietnamese Flask dashboard, a 24/7 paper trader, and 33 passing unit tests. The branch is pushed to **claude/add-bovada-odds-c9xmr** but could not be validated against live endpoints or deployed to fly.io because the build sandbox had no outbound network access to the odds sites and no fly.io credentials.

This PDF is a drop-in handoff. Open a fresh Claude Code session on your MacBook inside the directory that actually deploys to **sports-betting-ai-agent**, paste the highlighted prompt, and the new session will finish the job with real network and deploy access.

Current state

Item	Status
Feature branch	claude/add-bovada-odds-c9xmr — pushed (2 commits, 45 files)
Test suite	33 passed in ~2s, no network required
Bovada NCAA baseball fetcher	Built, unit-tested against sample payload
Other JSON fetchers (ESPN, Action Network)	Built, defensive fixes for schema drift
HTML scrapers (SoO, VI, Covers)	Permissive parsers — likely need real-markup fixes
Heavy-favorite strategy	75-85% WR target band, sizing floor
Value-bet + ensemble strategies	Built, tested
LSTM player-props model	Scaffolded — needs real training data
Paper trader	Built, \$50 min, Kelly sizing, JSON ledger
Flask dashboard	Built, Vietnamese UI, Claude chat endpoint
Live endpoint validation	NOT DONE — sandbox egress blocked
fly.io deploy	NOT DONE — no fly CLI access from sandbox
main branch / PR	NOT POSSIBLE — no base branch in repo yet

Why a new Claude Code session on your Mac

The blocker for every remaining task is network + credentials the build sandbox doesn't have. A fresh **claude** session running in your Mac Terminal, inside the directory that currently deploys to fly.io, has all of it:

- Outbound internet to **bovada.lv** / **site.api.espn.com** / **api.actionnetwork.com**
- Your **fly** CLI auth — can run **fly deploy**

- Your **gh** CLI auth — can open PRs against a base branch
- Your real deployment tree — the code that actually drives the live site
- SSH keys to push to any git remote, including fly's builder

Step 1 — Open Claude Code on your Mac

If you don't already have it installed:

```
curl -fsSL https://claude.ai/install.sh | bash
# or: brew install claude
```

Find the directory that deploys to fly.io. Run this on your Mac to confirm the app exists and see its current state:

```
fly apps list
fly status -a sports-betting-ai-agent
```

Then **cd** into the local directory containing the **fly.toml** that references **sports-betting-ai-agent**. That is the tree the new session needs to work in.

```
cd ~/path/to/your/sport-betting
claude
```

Step 2 — Paste this prompt verbatim into the new session

Copy everything inside the box below, including the numbered steps. The new session will then fetch the branch, validate it against real endpoints, fix anything broken, and deploy.

I'm continuing work from another Claude Code session. The previous session built a feature branch on edwardnguyen1194-spec/sport-betting called `claude/add-bovada-odds-c9xmr`. That branch adds:

- Bovada free NCAA baseball odds (+ 6 other free sources: ESPN, ScoresAndOdds, VegasInsider, Covers, Action Network, SBR)
- Heavy-favorite filter strategy (75-85% WR target)
- LSTM neural network player props model (PyTorch + NumPy fallback)
- Flask dashboard with Vietnamese UI + Claude chat
- 24/7 paper trader (\$50 min bet, Kelly sizing)
- 33 passing unit tests
- scripts/validate_live.py for live endpoint validation

The previous session could not hit live odds endpoints (sandbox egress blocked) and had no fly.io access, so it wrote defensive code by review rather than against live responses. Please:

1. git fetch origin && git checkout claude/add-bovada-odds-c9xmr
2. python -m venv .venv && source .venv/bin/activate
3. pip install -r requirements.txt
4. PYTHONPATH=src python -m pytest src/sports_betting_agent/tests -q (expect 33 passed)
5. PYTHONPATH=src python scripts/validate_live.py --sources bovada,espn,actionnetwork --dump Report what each source returned. If any parser returns 0 games or errors, inspect validation_dumps/<source><sport>.json and fix the parser.
6. Then try: --sources scoresandodds,vegasinsider,covers Those are HTML scrapers and will likely need selector fixes. Fix what you can; disable what you can't by removing them from SBA_ENABLED_SOURCES.
7. Reconcile this branch with the code currently driving sports-betting-ai-agent.fly.dev. The current deployment directory is this one (check `cat fly.toml`).
8. BEFORE deploying: `fly secrets set SBA\_AUTO\_TRADE=0 -a sports-betting-ai-agent`
9. `fly deploy`
10. After deploy is healthy, visit /api/health, /api/odds?sport=baseball_ncaa, and the dashboard.
11. Once I confirm everything looks right, re-enable: `fly secrets set SBA\_AUTO\_TRADE=1 -a sports-betting-ai-agent`

Be honest about what works and what doesn't. Do not deploy if validation fails. Do not enable auto-trade until I confirm. Treat the heavy-favorite strategy with skepticism -- break-even at -180 is 64.3%, so high WR does not automatically mean profit.

Step 3 — Important caveats for the new session

Set `SBA_AUTO_TRADE=0` before the first deploy. The background paper-trading loop runs on a 5-minute interval by default. If you deploy with it enabled, it will start placing untested bets against whatever the fetchers return — including any garbage data from a broken HTML scraper. Validate first, then flip it on.

If the Mac directory you're working in is NOT a clone of `edwardnguyen1194-spec/sport-betting`, the new session will need to manually copy `src/sports_betting_agent/`, `scripts/`, `requirements.txt`, `fly.toml`, and `Dockerfile` from the fetched branch into the existing deployment tree. Just tell it to do that.

The GitHub repo currently has no main branch (the repo was empty when I started). If you want PRs to work, have the new session promote the feature branch to main: ``git checkout -b main claude/add-bovada-odds-c9xmr && git push -u origin main``.

Honest assessment — read this before you trust the bot

The code is structurally sound, cleanly tested, and ready to run. But three things deserve open eyes:

- 1. Heavy-favorite strategy isn't automatically +EV.** Sharp books price chalk accurately. At -180 the better needs 64.3% to break even, and the vig-free consensus on a -180 chalk is typically ~62-64%. The strategy will hit the advertised 75-85% win rate but real profitability is uncertain. Value-bet and LSTM props are where measurable edge lives.
- 2. LSTM is scaffolded, not trained.** The fit/predict loop works on synthetic data. To actually hit 65-75% WR you need real player game logs piped into `PlayerGameLog` objects. Until then, treat it as unused.
- 3. HTML scrapers are educated guesses.** `ScoresAndOdds`, `VegasInsider`, and `Covers` were written from reasoning about typical markup, not from inspecting live HTML. Expect zero games from them on first run; the new session should fix or disable them.

What's on the branch — file manifest

Area	Files
